

FASHION IMAGE GENERATION WITH AUXILIARY CLASSIFIER – GENERATIVE ADVERSARIAL NETWORK MODELS

Steve Desilets

MSDS 458: Artificial Intelligence and Deep Learning

December 3, 2023

1. Abstract

Image generation applications, which have dramatically improved in sophistication in recent years, have been captivating the public's attention and transforming the way that people create artistic content. In this study, we apply one such computer vision model – the Auxiliary Classifier Generative Adversarial Network (AC-GAN) model to the MNIST Fashion dataset to create ten generative AI applications capable of creating images of clothing. As we create these AC-GAN models we explore the impacts of model architecture and regularization design choices on model performance, and we discover one such model that provides promising evidence that AC-GAN models could serve as useful tools for generating images that correspond to a variety of object classes.

2. Introduction

Image generation applications like Stable Diffusion, Midjourney, and DALL-E have skyrocketed in popularity since their recent releases – helping users create media content, develop educational materials, and accelerate marketing campaigns. Inspired by these visionary companies, we focus this study on developing and evaluating the effectiveness of 10 image-based generative AI algorithms that can help accomplish similar content creation tasks for users. Specifically, we leverage the publicly available Modified National Institute of Standards and Technology (MNIST) Fashion Dataset, which contains 60,000 training and 10,000 testing images of fashion-related articles published by Zalando Research (Zalando Research 2017). Each observation consists of 28 x 28 pixel, greyscale images that correspond to one of the 10 fashion-related classes defined in Table 1 below. Utilizing this fashion dataset, we create ten Auxiliary Classifier – Generative Adversarial Network (AC-GAN) models while leveraging varying model architecture and regularization techniques, so that we can discover the impacts of these model design choices on the ability of these models to create realistic fashion images.

Table 1: Image Classes and Corresponding Labels in the MNIST Fashion Dataset

Class Label in MNIST Fashion Dataset	Class Description
0	T-Shirt or Top
1	Trousers
2	Pullover
3	Dress
4	Coat
5	Sandal
6	Shirt
7	Sneaker
8	Bag
9	Ankle Boot

3. Literature Review

Researchers have been exploring the intersection of art and computing for decades, and their efforts have laid the groundwork for this study’s analyses of AC-GAN models. This research began as early as the 1960’s when artist and engineer Harold Cohen first developed AARON – a computer system capable of generating art by instructing a small robot equipped with a marker (known as a “turtle”) about how it should move on a page (Garcia 2016). While AARON was artistically significant in raising important questions about art, AARON was still technologically simple since it required all new styles and imagery to be hard-coded by Cohen and since it could not independently learn (Wikipedia 2023). The sophistication of image-based generative AI technology began rapidly accelerating in 2014 after Dr. Ian Goodfellow invented the Generative Adversarial Network (GAN). This model pitted two neural networks – one image generator and one image discriminator – against one another (Giles 2018). By iteratively training each model, the neural networks would grow increasingly sophisticated until the generator finally would create highly realistic images. Three years later, a group of researchers introduced the first AC-GAN model – which built upon existing GAN models whose discriminators solely discriminated between real and fake images by adding a second classification layer to discriminate between classes of images (Bandyopadhyay 2020). This added discriminator layer enabled the AC-GAN model to learn to generate more sophisticated images across a broad array of classes. As early as 2019, data scientists began applying this newly developed AC-GAN technology to the MNIST Fashion dataset

and achieved admirable results in creating realistic images of clothing (Brownlee 2019). While the successes of all these researchers are quite admirable, in this paper, we hope to build upon their success by constructing many AC-GANs with varied architecture and regularization design choices to optimize the fashion image generation performance of these models as much as possible.

4. Methods

After clearly defining our business objective and conducting the background literature review, we kicked off our experimentation with the MNIST Fashion dataset, and the first phase of this process was exploratory data analysis. Accordingly, we first imported the MNIST fashion dataset and explored its characteristics like the number of observations in the training and testing datasets (which were 60,000 and 10,000, respectively). We also created a histogram to visualize the number of observations that correspond to each of the fashion categories and found that the observation counts were evenly distributed across the 10 classes. Subsequently, we examined the data quality by visualizing a subset of 100 of these greyscale images. Inspection of these images revealed that the data appeared to be of sufficient quality to empower us move forward with creating AC-GAN models using this dataset.

In the next phase of our study, we constructed ten different AC-GAN models. The goals of this phase were to: 1) determine whether AC-GAN models could be used to generate realistic images of fashion-related objects and 2) assess the impact of model design choices on AC-GAN model performance. Collectively, addressing these two objectives would empower the research team to understand how to build an AC-GAN that creates images that are as realistic as possible across image classes. For the first experiment, we developed a baseline AC-GAN model that included a discriminator with four convolutional layers and a generator with two convolutional 2D transpose layers. In the second experiment, we strived to determine whether altering the model architecture by increasing the dimensionality of the latent space from 100 to 200 nodes would improve model performance. For the third experiment we shifted our attention to examining whether increasing the number of epochs leveraged while fitting the model could improve the model's usability. In the fourth experiment, we aimed to build upon the success of previous models by doubling the number of training epochs and by

introducing regularization. Specifically, we aimed to assess the impact on model performance of decreasing the AC-GAN’s learning rate parameters from 0.002 to 0.001. For the fifth experiment, we aimed to see whether the model could benefit from adjusting the hyperparameters to address potential underfitting. Consequently, we decreased the dropout rate in the model’s discriminator from 0.5 to 0.35 to determine the impact of such an adjustment on model performance. After enduring the long training time of over 3.5 hours for the fifth model, we aimed to examine the impact of batch size on model performance for the sixth model. In this sixth experiment, we were interested in whether increasing the batch size from 64 to 128 would have noticeable impacts on model performance or on training time. For the seventh model, we pivoted our attention to assessing the impacts of another important hyperparameter: discriminator convolutional layer stride sizes. Specifically, we evaluated whether decreasing the stride sizes from (2,2) to (1,1) would empower the discriminator to perform with greater accuracy and consequently improve the AC-GAN model. For the eighth model, we focused our attention on the impacts of layer architecture on AC-GAN model performance. Accordingly, we removed one of the four 2-D convolutional layers from the discriminator model, so we could determine whether a simpler layer architecture could improve performance. For the ninth experiment, we evaluated the impacts of adjusting the AC-GAN model’s momentum hyperparameters from 0.5 to 0.9 to see whether returning this parameter to its default levels could improve outcomes. For the tenth and last model, we re-focused our attention on the impact of the number of epochs on model performance. While we were not able to run the first nine models with as many epochs as desired (due to time constraints), we set the number of epochs to be as high as we could for this model to assess the impacts of giving the AC-GAN more time to appropriately train itself using the massive amount of available data.

After constructing each of these 10 AC-GAN models, we evaluated the effectiveness of each model via both quantitative and qualitative assessments. To conduct qualitative assessments, we first generated 100 images from the resulting model and randomly selected 100 images from the MNIST Fashion dataset. Then, we manually conducted pairwise comparisons between 100 pairs of these images – picking which image to be more realistic in each match-up. After completing this process, we

calculated the percentage of sampled fake images that were more realistic than real MNIST Fashion images. We also conducted further qualitative assessments by reviewing the 100 generated images for evidence of mode collapse, which occurs when a generator repeatedly generates the same image and the discriminator fails to learn to identify it as fake. To conduct quantitative assessments, we calculated and reviewed a commonly used performance metric for assessing AC-GAN models – called the inception score – for each model. Additionally, we calculated the time to fit each model, since the time to fit such sophisticated models could be a significant limiting factor for organizations interested in such generative AI applications. Through these experiments and the qualitative / quantitative reviews of their results, we aimed to determine whether AC-GAN models could be optimally tuned to generate realistic images across an array of object classes.

5. Results

The primary takeaway from the results of the first model is that our first AC-GAN model was able to successfully generate images based on what it had learned from the MNIST Fashion dataset. Though many of the sample images generated by this model (as displayed in Appendix B) were very blurry, they still suggested an extremely exciting finding: that these AC-GAN models, if properly tuned, could work for our desired objective. Despite the blurriness of the model’s generated images and the low inception score of 1.127, there were some other positive findings as well. Specifically, this baseline model managed to produce images that looked more realistic than 2% of the sampled MNIST images. Furthermore, since the model was not repeatedly generating the same fake image, there was no evidence of mode collapse in the results. One last very significant finding from this model was that this introductory single-epoch model took over 13 minutes to fit. Given that we would ideally like to have dozens of epochs to fit such a model, the runtime to fit this model served as a bright warning sign that we would need to be cautious about how much time we’d have to fit the models for this study.

The second experiment, which adjusted the model architecture by increasing the dimensionality of the latent space from 100 to 200 nodes, produced quite interesting results. Perhaps the most interesting finding was that the resulting generated images resembled Rorschach inkblot tests perhaps more than any

other model’s generated images did. In that sense, the contrast in these images was quite high. Still, increasing the complexity of the model architecture did not seem to improve the model results. The percentage of generated images deemed more realistic than actual images fell from 2% to 0%, and the inception score remained low at 1.15. The main positive finding was just that this was the fastest model to fit (by far) at 9 minutes and 20 seconds. As a result of these lukewarm findings, future AC-GAN models returned to using a 100-dimensional latent space.

In many ways, increasing the number of epochs from 1 to 3 for the third experiment produced the exact results that one would expect. The time to fit the model (27 minutes) was triple that of previous models, and the quantitative performance metrics rose as well. The inception score reached a new high of 1.191 and the percentage of generated images deemed more realistic than real images rose back up to 2%. The qualitative review of the generated images also revealed that these images were less blurry than the images generated by previous models. Furthermore, the fact that the generated images exhibit no evidence of mode collapse builds our confidence that more epochs should result in greater model performance.

For the fourth model, we not only built on the third model’s success by doubling the number of training epochs to 6, but also examined the impacts of regularization on AC-GAN model performance. Specifically, decreasing the model’s learning rate hyperparameters from 0.002 to 0.001 seemed to generate some positive outcomes. The percentage of generated images deemed relatively realistic increased to 3% and the inception score ticked up to 1.218. Both of these were new high levels, though notably, they did remain low compared to the maximum possible values of 100% and 10. Another significant finding was that, as expected, doubling the number of epochs also doubled the training time to a new high of 1:02:29. In subsequent models, we would leverage these findings about appropriate learning rates and the utility of extra epochs to guide how we set these values, so we could further improve the model results.

For the fifth model, which focused on adjusting the dropout rate from 0.5 to 0.35 so that the model could potentially address the possibility of underfitting, the most startling finding was not the

performance metrics but the training runtime. The time to fit this model increased to a jarring new high of 3:37:41 despite the number of training epochs remaining unchanged at 6. The actual performance evaluation results were quite muted in comparison to that computational finding. The inspection score rose slightly to 1.218, the percentage of generated images deemed relatively realistic fell slightly to 2%, and there was no evidence of mode collapse. Qualitatively, many of the images looked less blurry than images generated by previous models, but often didn't resemble clothes. These findings suggest that adjusting the dropout rate did not have a strong impact on model performance, so we set it back to 0.5 in future models to mitigate the risk of overfitting to our large training dataset.

The sixth model, for which we increased the batch sizes during training from 64 to 128, produced mixed results. Computationally, this model produced much better performance metrics than the fifth model as evidenced by the training time falling by 71% down to 1:04:14. While this decrease in runtimes was incredible, the increased batch size also (as expected) decreased model performance. The percent of model-generated images deemed relatively realistic fell to 0% and the inception score dropped to 1.204. As a consequence of these quantitative performance measures falling, for future models, we returned to leveraging batch sizes of 64 – even if that did mean accepting that we'd experience longer training times.

The results of the seventh model, for which we decreased the discriminator convolutional layer strides from (2,2) to (1,1) produced some extreme results. As expected, the runtime for this model increased – though the runtime skyrocketed to even longer levels than we had anticipated. The training time for this model was a staggering 3:49:51 – the longest training time of any of the 10 models. This increased training time did result in some positive performance impacts. Specifically, the resulting images exhibited no signs of mode collapse and were less blurry than images generated by previous rounds. Furthermore, the inception score reached the highest level of all 10 models – 1.228. Despite these successes, the percentage of generated images deemed relatively real only reached 1%. In this way, the increase in training time caused by decreasing the strides simply did not result in strong enough improvements in performance to justify keeping the strides at (1,1) for the final 3 models.

The key finding from the eighth AC-GAN model experiment was that the removal of a 2D-convolutional layer from the discriminator decreased model performance. Quantitatively, this manifested as a decrease in the inception score down to 1.221 and a decrease in the percent of generated images deemed relatively realistic down to 0%. On the qualitative side, this decrease in performance manifested as the generated images being blurrier than the images generated by previous models. Collectively, these findings suggested that the additional 2-D convolutional layer in the first 7 AC-GAN models had been serving an important role, so we added this layer back in for the last two AC-GAN models constructed.

The results of the ninth AC-GAN model, for which we increased the momentum hyperparameters from 0.5 to 0.9, were very similar to the results of the eighth AC-GAN model. The training time for this model remained at a relatively reasonable level (1:12:58), and the generated images suggested no evidence of mode collapse. Still, the results did leave room for improvement. Specifically, the inception score fell a bit to 1.21 and the percentage of generated images deemed relatively realistic remained at 0%. Despite these not-so-promising quantitative measures, on a purely anecdotal level, we did think that many of model 9's generated images looked better than the images generated by prior models.

For the tenth and final model, for which we refocused our energy on the epochs hyperparameter – increasing the number of epochs to a new high of 15 – the results were relatively strong. As expected, the training time to fit this model did spike quite a bit up to 2:46:59 – the third longest training time of any of our models. However, the other quantitative KPIs delivered improved results. This model resulted in the second highest inception score of 1.224 and the highest percent of generated images deemed relatively realistic of 7%. Anecdotally, this model really seemed to begin to understand the silhouette of certain articles of clothing like dresses, t-shirts, ankle boots, and sneakers. Furthermore, our heighted fears of mode collapse (due to the increased epochs) did not materialize in the generated images, which was a great finding as well. Overall, this was probably the best of the ten models constructed, but certainly suggested that with additional computational power / time, the AC-GAN model could be further improved by training the model with even more epochs.

6. Conclusions

The images generated by each of the AC-GAN models that we trained throughout our research suggest that properly tuned AC-GAN models could serve as useful tools for generating images corresponding to a broad array of classes. Furthermore, we find that model architecture and regularization design choices can have important impacts on the quality of generated images as well. If I were the lead data scientist accountable for advising a tech company whether to launch one of these image generation applications, I would advise them to strongly consider conducting further research to improve model performance to find a model that generates images more realistic than real images more than 7% of the time. Specifically, I would emphasize that areas for future research should include: leveraging more computational power so that researchers can run more epochs when fitting the models, finding ways to detect the Vanishing Gradient Problem (when the discriminator is too much better than the discriminator, so the discriminator fails to improve), and exploring options to leverage pre-trained image generation models like DALL-E or Stable Diffusion. By better addressing these areas for future research, the tech company could certainly construct an AC-GAN model even more successful than the 10 that we constructed here. That said, if the client needed to launch one of these AC-GAN models, I would recommend utilizing the tenth model since it achieved the highest qualitative ratings and the second highest inception scores of all ten models constructed.

Appendix B – Sample Generated Images

Below, we display 100 fashion images generated by each of the 10 models after completing the training process for each of the AC-GAN models. These were the images leveraged to conduct the qualitative evaluations of how realistic the model-generated images appeared compared to randomly selected images from the MNIST Fashion dataset. The code leveraged to generate these images is available in Appendix C.

1) Introduction and Exploratory Data Analysis

Let's import the MNIST Fashion Dataset and conduct exploratory data analysis.

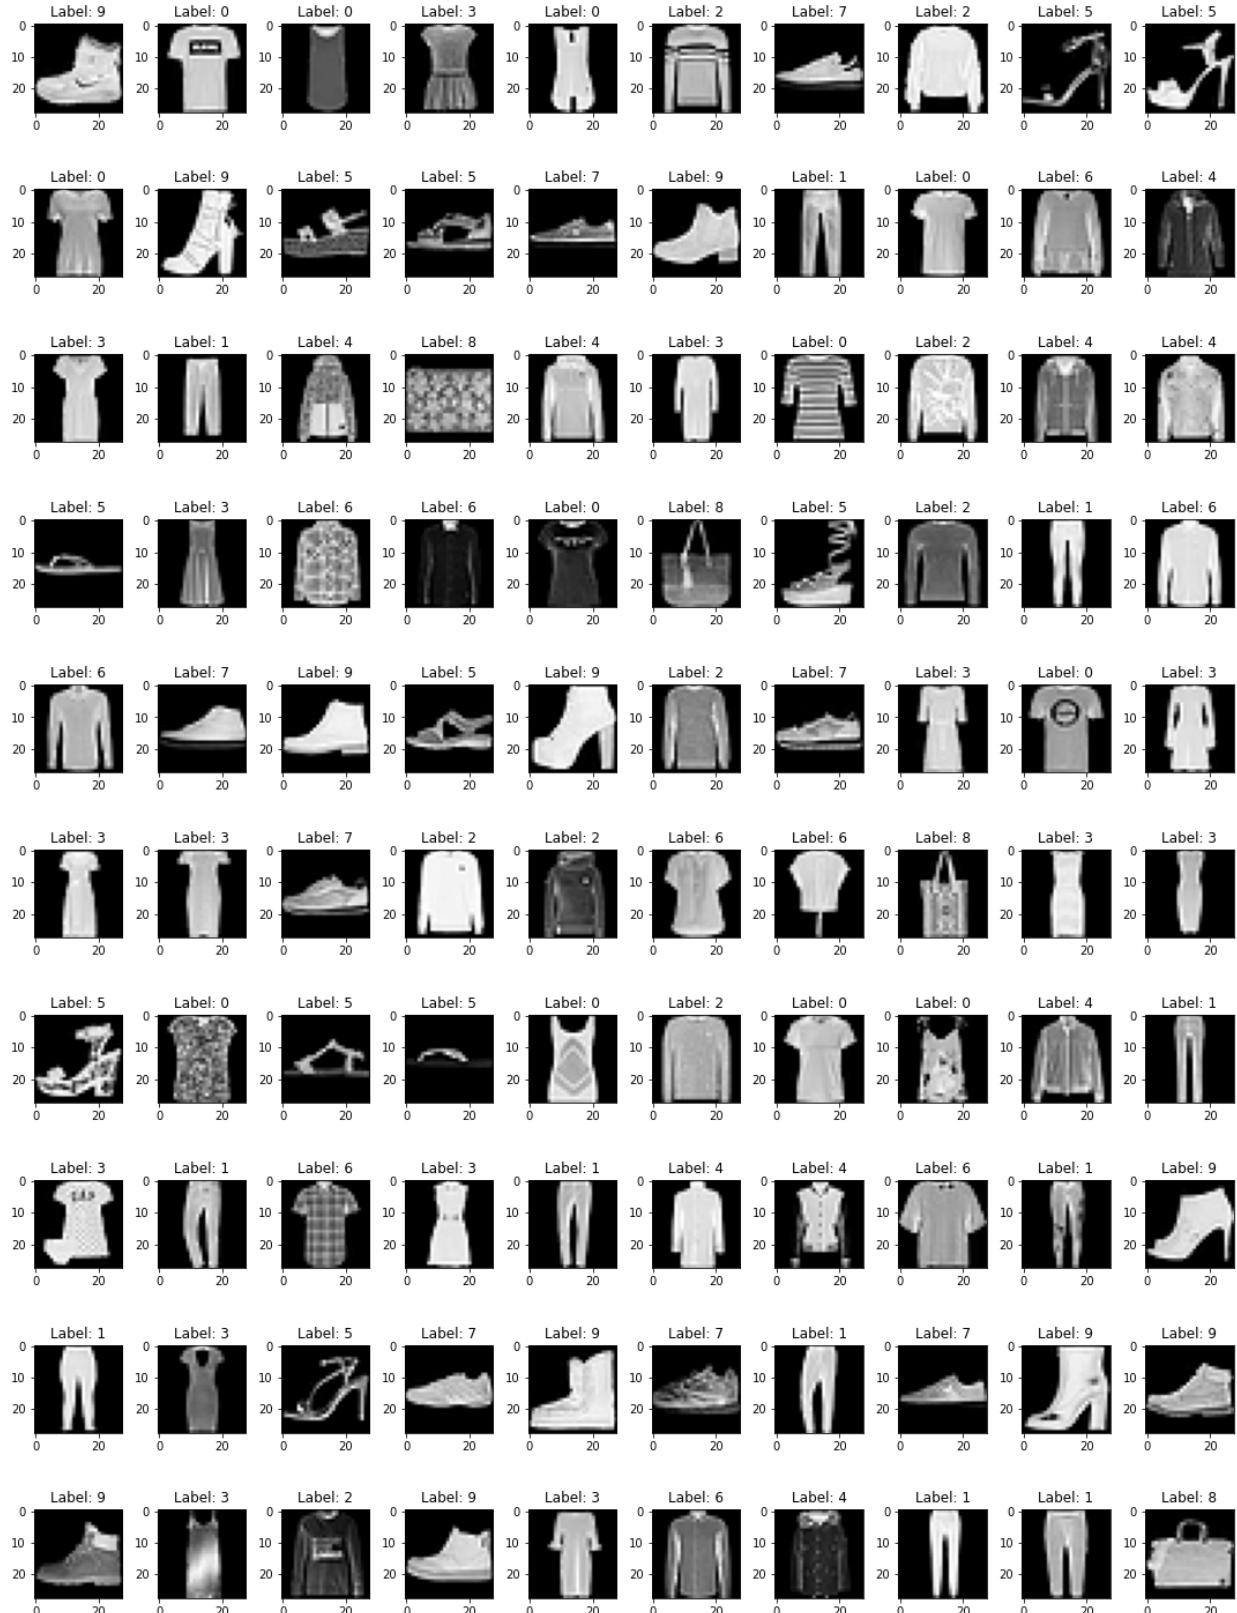

```
In [24]: from tensorflow.keras.datasets import fashion_mnist  
  
(X_train_eda, Y_train_eda), (X_test_eda, Y_test_eda) = fashion_mnist.load_data()  
print('Fashion MNIST Dataset Shape: ')  
print('X_train: ' + str(X_train_eda.shape))  
print('Y_train: ' + str(Y_train_eda.shape))  
print('X_test: ' + str(X_test_eda.shape))  
print('Y_test: ' + str(Y_test_eda.shape))  
  
Fashion MNIST Dataset Shape:  
X_train: (60000, 28, 28)  
Y_train: (60000,)  
X_test: (10000, 28, 28)  
Y_test: (10000,)
```

```
In [25]: import matplotlib.pyplot as plt  
%matplotlib inline
```

Let's visualize sample images from our dataset

```
In [28]: # specify the number of rows and columns you want to see  
num_row = 10  
num_col = 10  
  
# get a segment of the dataset  
num = num_row*num_col  
images_eda = X_train_eda[:num]  
labels_eda = Y_train_eda[:num]  
  
# plot images  
fig, axes = plt.subplots(num_row, num_col, figsize=(1.5*num_col, 2*num_row))  
for i in range(num_row*num_col):  
    ax = axes[i//num_col, i%num_col]  
    ax.imshow(images_eda[i], cmap='gray')  
    ax.set_title('Label: {}'.format(labels_eda[i]))  
plt.tight_layout()  
plt.show()
```

Appendix - Supporting Python Code

Let's create a graph to display the number of observations that correspond to each of our 10 categories (as outlined below).

Label In MNIST Fashion Dataset	Description
0	T-Shirt Or Top
1	Trousers

Label In MNIST Fashion Dataset Description

2	Pullover
3	Dress
4	Coat
5	Sandal
6	Shirt

3) Model 2 - Experimentation with Dimensionality of AC-GAN's Latent Space

3.1) Build The Model

Let's construct and train the AC-GAN model. For this model, we will try to improve performance by modifying the first model by having a 200-dimensional latent space instead of a 100-dimensional latent space.

```

In [11]: # example of fitting an auxiliary classifier gan (ac-gan) on fashion mnsit
from numpy import zeros
from numpy import ones
from numpy import expand_dims
from numpy.random import randn
from numpy.random import randint

```

```
